Introduction

The phenomenon in which reducing sugars such as glucose bind to protein non-enzymatically to form glycoproteins is known as glycation. Glycation stress refers to a form of stress on the body caused by a load of reducing sugar or aldehyde. As an aging risk factor, glycation stress can serve as a promoter of skin aging, diabetic complications, and other conditions. Available methods of glycation stress reduction include the suppression of hyperglycemia, the suppression of glycation reactions, and the degradation and excretion of glycation reaction products.

We previously assessed the effects of choice of staple food and the addition of dietary fiber on changes in postprandial blood glucose levels, showing that adding dietary fiber in advance suppresses blood glucose level elevations after meals. However, the staple food cooked rice tends to produce greater elevations of blood glucose levels than pasta; there may be much room for improving the way of eating cooked rice in relation to other foods. Before starting the present study, we hypothesized that blood glucose level elevations could be suppressed by taking a staple food and a side dish in combination. In addition, provided that the difference in postprandial blood glucose level among different staple foods is lessened by taking a staple food and a side dish in combination, a glycation stress suppressing effect may be achieved by combining a staple food, even if chosen freely, with an appropriately chosen side dish. In the present study, we assessed the effects of choice of staple food and its combination with various side dishes on changes in postprandial blood glucose levels, with the aim to develop a method of reducing glycation stress from the viewpoint of suppression of hyperglycemia.
Methods

Subjects

Subjects were recruited from among those with relevance to the Department of Anti-Aging Medicine, Doshisha University Faculty of Life and Medical Sciences, as in the previous study. The subject inclusion criteria comprised healthy persons aged 20 years or older who did not meet any of the following exclusion criteria: those with food or drug allergy, pregnant or lactating women, patients under treatment with medication or follow-up, patients with the diagnosis of diabetes mellitus, patients with a pronounced cardiopulmonary functional disorder, patients on therapeutic medication for hypertension, persons with a past history of gastrointestinal surgery, and persons suspected of having infectious disease. Other subjects judged by the investigator as being inappropriate for inclusion in the study were also excluded from the study.

The study population comprised 19 subjects with relevance to Anti-Aging Medical Research Center, Doshisha University Faculty of Life and Medical Sciences (9 males and 10 females, age 30.3 ± 12.0 years, BMI 20.8 ± 2.5). These subjects provided written consent to participate in the study after being given a full explanation of the study.

Protocol for blood glucose test

A blood glucose test was performed according to the unified protocol established by the Japanese Association for the Study of Glycemic Index (JASGI) as reported previously.

On the day before the test, excessive exercise, taking meals after 8:00 p.m., surfeit, overdrinking, and staying up late at night were prohibited. If the subject felt ill on the day before the test, or prior to or during the test, the test was postponed or terminated.

On the day of the test, the reference diet and each test food were taken over a period of 5-10 minutes, with about 30 chews per mouthful. Blood glucose was measured at 15 (2nd time), 30 (3rd time), 45 (4th time), 60 (5th time), 90 (6th time), and 120 minutes (7th time) after the start of food ingestion (taking each test food). Each subject measured glucose levels using a glucose meter for self monitoring (GLUCOCARD MyDia, ARKRAY, Inc., Kyoto).

Test foods

The reference diet and test foods used in the present study are listed in Table 1. Nutrient contents in some of these foods were calculated using the Standard Tables of Food Composition in Japan 2010.

Handmade udon and ingesting indigestible dextrin-blended udon (udon supplemented with dietary fiber) were used as staple foods, with cooked rice serving as the reference diet, as reported in the previous study. These materials were supplied by Hanamaru, Inc. (Chuo-ku, Tokyo, Japan). Thereafter, the influence of side dishes on blood glucose levels were assessed using udon with a soft boiled egg (Japanese common name “ontama udon”), vegetable udon (Japanese common name “salad udon”), a bowl of rice topped with braised meat and eggplant (mabonasu) (cooked rice + mabonasu), and udon topped with mabonasu.

Udon: thick Japanese wheat flour noodle. Udon with a soft boiled egg: commonly called “ontama udon. Braised meat and eggplant: mabonasu. Numerical figures for food items shown in black were calculated using the Standard Tables of Food Composition in Japan 2010. Numerical figures for food items shown in red were calculated using the nutritional facts indicated on the respective labels.
Glycative Stress Research

(udon supplemented with dietary fiber + mabonasu), which were selected from among recipes recommended by the collaborating udon manufacturer.

The amount of carbohydrates other than dietary fiber in each test food was set at 75 ± 10 g in order to correspond to the 75 g amount of carbohydrates other than dietary fiber for the 75 g oral glucose tolerance test (OGTT) in common use for diagnosing diabetes mellitus, except for kakeudon (wheat noodles served hot in broth), ontama udon, and salad udon, taken alone, which were used exactly in the amounts indicated on their labels to reflect the recipes shown by the udon manufacturers. The amount of carbohydrates other than dietary fiber was obtained by subtracting the amount of dietary fiber from the amount of carbohydrates.

Of the foods used in the experiments, udon and udon supplemented with dietary fiber were supplied by Hanamaru, Inc. Packed cooked rice (Sato No Gohan; Sato Foods Co., Ltd., Niigata, Japan) was used as reference diet. Retort-packed sauce packs (Mabonasu No Moto; Marumiya, Suginami-ku, Tokyo, Japan) were used for braised meat and eggplant.

Statistical analyses

The 0-minute value was subtracted from the blood glucose level measured over time after eating each test food to obtain Δblood glucose level; the largest change in the level observed up to 120 minutes after the start of ingestion was considered as the maximum blood glucose level change. Using these parameters, the area under the blood glucose elevation curve (AUC) was calculated. Data obtained were statistically analyzed by the Mann-Whitney U-test for significant differences between 2 groups and Tukey’s multiple comparison test among 3 groups or more, using the SPSS statistical analysis software. A two-sided p-value of less than 5% was considered to indicate a significant difference.

Ethical Considerations

The present study was conducted in compliance with the ethical principles of the Declaration of Helsinki (Note of Clarification added at the 2004 World Medical Association General Assembly in Tokyo) and Japan’s Act on the Protection of Personal Information, and with reference to the Ministerial Ordinance on Good Clinical Practice (GCP) for Drug (Ordinance of Ministry of Health and Welfare No. 28 of March 27, 1997) and the Ethical Guidelines for Epidemiological Research established by Japan’s Ministry of Health, Labour and Welfare, and Ministry of Education, Culture, Sports, Science and Technology. The present study was conducted after examination and approval for the ethics and appropriateness of the study at a meeting of the Doshisha University Ethics Committee for Scientific Research Involving Human Subjects (Approval number # 1228).

Results

A comparison was made between kakeudon and ontama udon (kakeudon + soft boiled egg) and between kakeudon and salad udon (kakeudon + vegetables). Ontama udon produced no significant difference in maximum blood glucose level change, with a 27% smaller AUC (p = 0.029, Figs. 1 and 2), compared with kakeudon. Salad udon tended to have smaller maximum blood glucose level changes (p = 0.056), with a 28% smaller AUC (p = 0.023, Figs. 3 and 4), compared with kakeudon.

Influence of a combination of cooked rice or udon supplemented with dietary fiber and a shared side dish on blood glucose levels

When comparing cooked rice and udon supplemented with dietary fiber, udon supplemented with dietary fiber had a smaller maximum blood glucose level change of 17 mg/dL (p = 0.013), with a 20% smaller AUC (p = 0.046, Figs. 5 and 6), than cooked rice.

A bowl of rice topped with braised meat and eggplant (mabonasu) produced a 15 mg/dL lower maximum blood glucose level change (p = 0.046) and a 28% smaller AUC (p < 0.001, Figs. 7 and 8) than cooked rice taken alone.

When comparing udon topped with mabonasu and udon supplemented with dietary fiber taken alone, no significant difference was found, and the AUC was smaller by 28% with udon topped with mabonasu than with udon supplemented with dietary fiber (p = 0.034, Figs. 9 and 10).

In both the maximum blood glucose level change and AUC, no significant difference was found between a bowl of rice topped with mabonasu and udon topped with mabonasu (Figs. 11 and 12).

Discussion

In the comparative study of different staple foods reported previously, bread and pasta tended to produce lower values of both maximum blood glucose level change and AUC than cooked rice. Although a combination of cooked rice and a soup containing dietary fiber did not suppress changes in postprandial blood glucose levels, the addition of dietary fiber to udon was shown to lessen the elevation of blood glucose levels after meals. In the present study, the effects of the choice of side dish taken in combination with cooked rice on postprandial blood glucose level elevations were assessed.

The salad udon experiment showed that the amount of carbohydrates other than dietary fiber was greater by nearly 10 g in salad udon than in kakeudon. Despite this fact, concurrent ingestion of salad and udon revealed a blood glucose level reducing effect. It has already been reported that blood glucose level elevations are more largely suppressed by taking vegetable salad before taking cooked rice.

Dietary fiber contained in vegetables is known to delay sugar absorption by increasing viscosity of the content in the upper gastrointestinal tract via its gelation, and influencing the content movement rate as well as digestion and absorption in the gastrointestinal tract. It also inhibits sugar absorption by increasing viscosity of the content in the gastrointestinal tract. By adding braised meat and eggplant (mabonasu) as a side dish to each staple food, it is recommended that the side dishes taken contain dietary fiber, proteins, and lipids in a good balance, and they should also incorporate a vegetable possessing anti-glycation activity.

Conclusion

A combination of a staple food and side dishes may be more effective than low-GI foods in suppressing glycation stress. While it is an approach to suppressing glycation stress from meals to choose a staple food from among low-GI foods such as pasta, as well as udon supplemented with dietary fiber, even high-GI foods such as cooked rice are expected to be more effective than low-GI foods when combined with an appropriately chosen side dish.
Acknowledgments

A presentation of this study was made at the 13th Scientific Meeting of Japanese Society of Anti-Aging Medicine (Yokohama; June 2013), and it received the Best Poster Award selected by high school students. Test food samples were provided by Hanamaru, Inc.
